個人帳號(Personal Account)

與

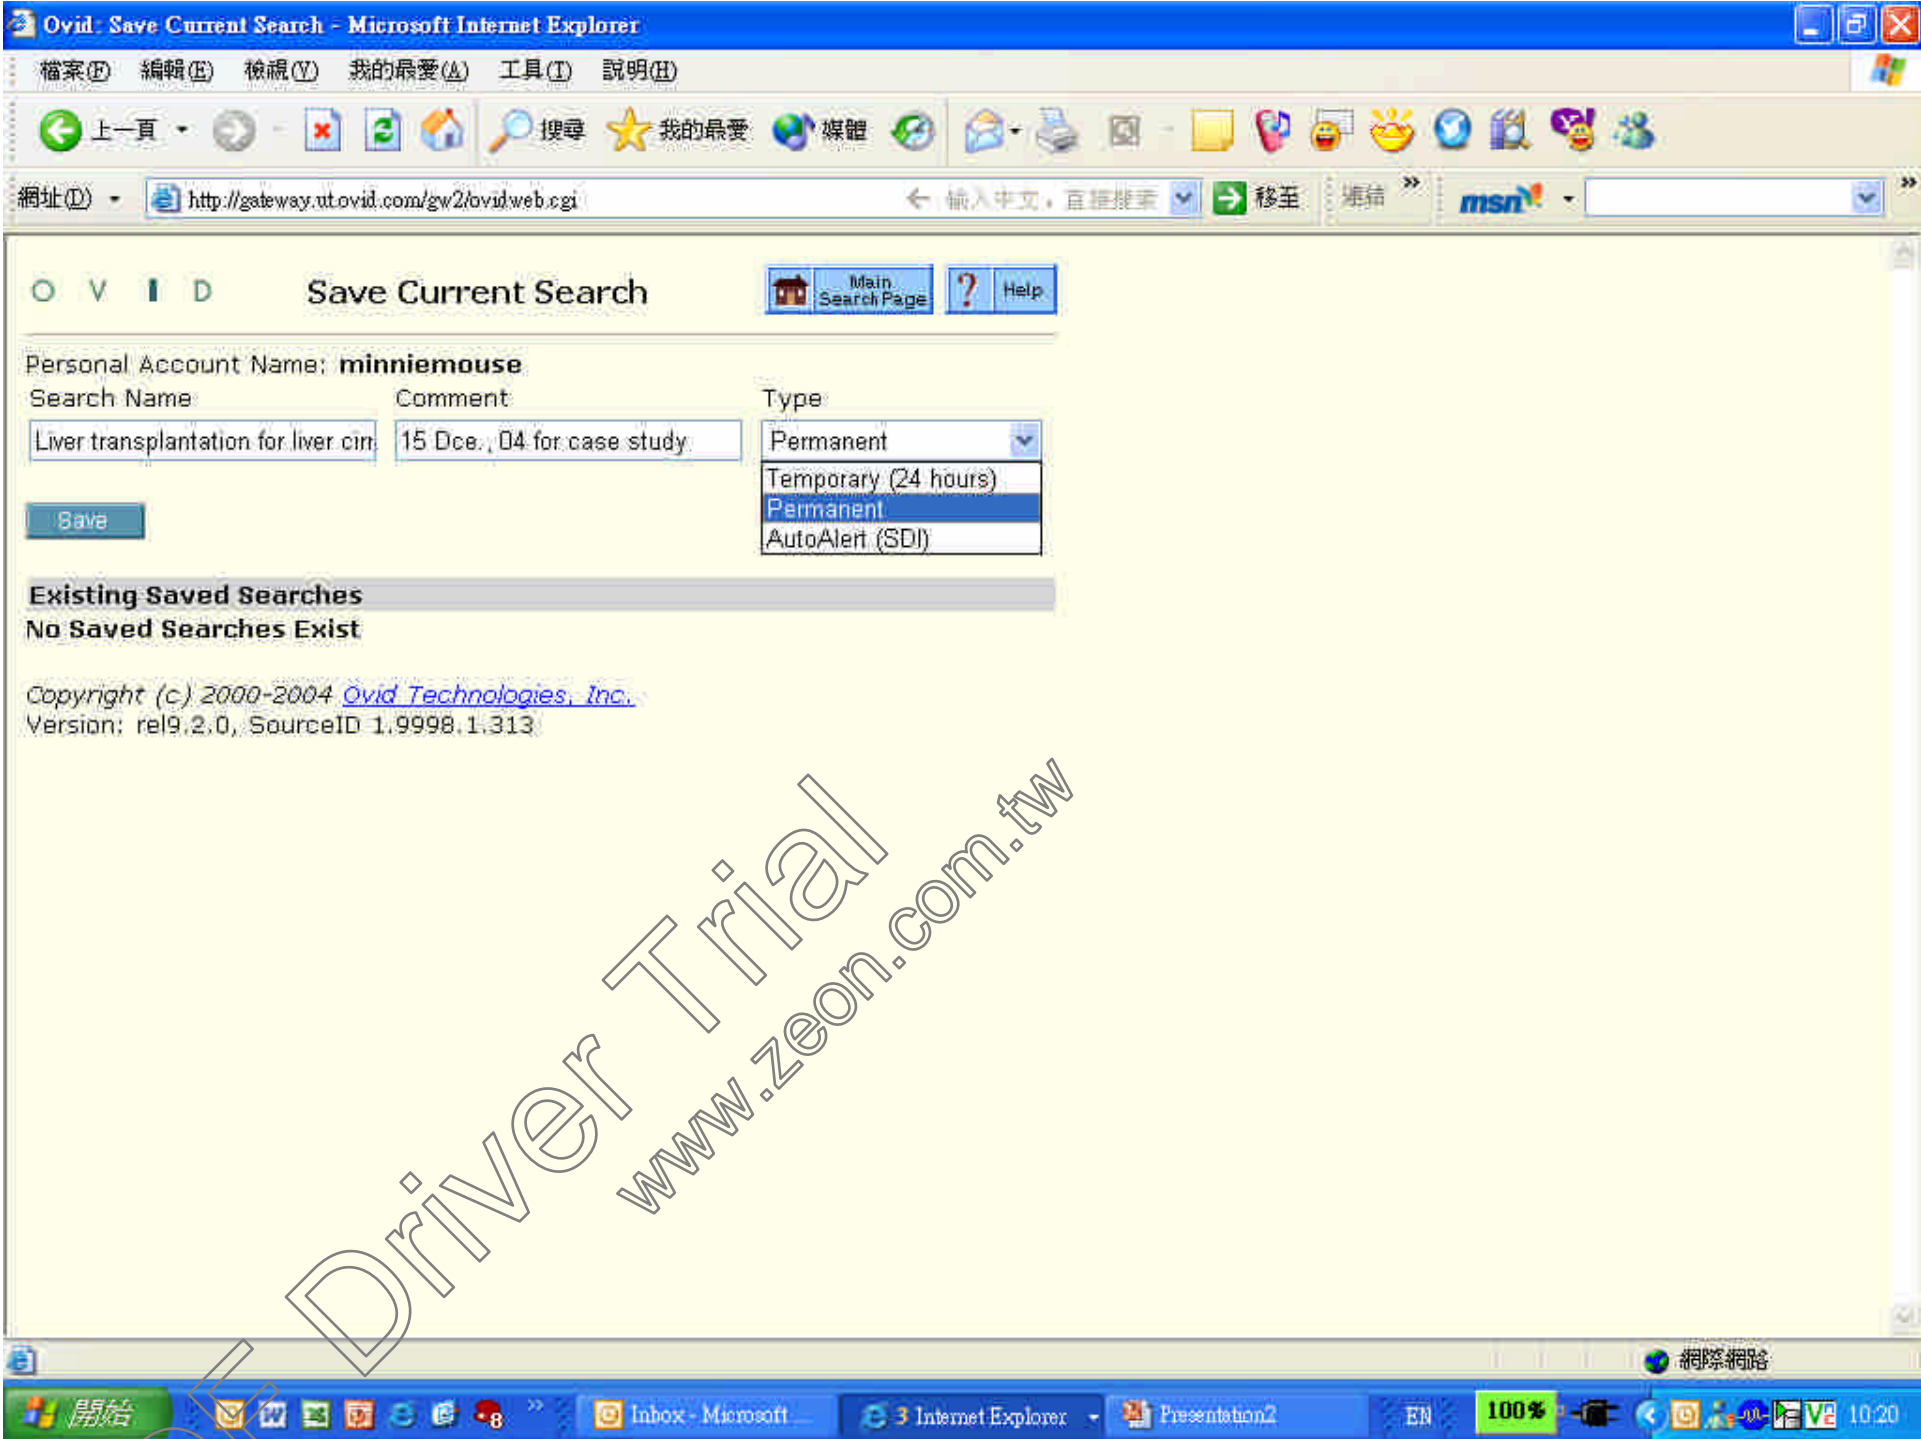

自動專題服務(AutoAlert)

的使用

PDF Driver Trial
www.zeon.com.tw

使用個人帳號(Personal Account)的好處：

- ⊕以不同的設定保存不同的檢索策略
- ⊕能隨時對已保存的檢索策略進行新的檢索與編輯
- ⊕使用自動專題服務(AutoAlert)
- ⊕更有效的管理多個檢索策略

Browse Journals (A-Z)

Browse Journals (Subject)

Hints:

- Choose **A-Z** option to browse an alphabetical list of available journals for known titles. From this list, you can view sets of journal names and issues. Choose **Subject** option to browse journals within a subject area. You can view a hierarchical display of subject categories and subcategories, choose journals from within these categories, and examine tables of contents of specific journal issues.
- From the issue list, you can examine issue tables of contents, and then link to the bibliographic record or full text (including graphics) of each article.
- Note that you will be able to see full tables of contents for each journal and bibliographic information for every available article, but you will only be able to see the full text of a journal's articles if you subscribe to it through Ovid.

A Narrow Complex Tachycardia in a Man With Palpitations for Many Years

[Featured ECG], Indik, Julia H, MD, PhD

From the University of Arizona, Sarver Heart Center, 1501 N. Campbell Ave., Tucson, AZ 85724. Reprints: Julia Indik, MD, PhD, University of Arizona, Sarver Heart Center, 1501 N. Campbell Ave., Tucson, AZ 85724. Email: jindik@email.arizona.edu

Abstract

Abstract: A case of a 19-year-old man with congenitally acquired HIV infection who was found to have a large intracardiac mass is presented. Presurgical imaging studies and subsequent pathologic findings and histology are discussed.

A 19-year-old man presented with fatigue and shortness of breath. Initial evaluation revealed an intracardiac mass by echocardiogram, and he was transferred for evaluation and treatment.

The patient's medical history was notable for congenitally acquired HIV. He had not sought medical care or taken any medications for 2 years before presentation, although antiretroviral therapy had been prescribed in the past. There was no history of opportunistic infections, and he had been well up until this presentation.

Abstract

Abstract: A case of a 19-year-old man with congenitally acquired HIV infection who was found to have a large intracardiac mass is presented. Presurgical imaging studies and subsequent pathologic findings and histology are discussed.

A 19-year-old man presented with fatigue and shortness of breath. Initial evaluation revealed an intracardiac mass by echocardiogram, and he was transferred for evaluation and treatment.

The patient's medical history was notable for congenitally acquired HIV. He had not sought medical care or taken any medications for 2 years before presentation, although antiretroviral therapy had been prescribed in the past. There was no history of opportunistic infections, and he had been well up until this presentation.

On transfer, it was noted that shortness of breath had increased over 3 months and was occurring with minimal exertion. He had additionally experienced palpitations and occasional fever, but denied chest pain, orthopnea, or weight loss. There was no family history of cardiac masses.

Examination revealed a hyperdynamic apical impulse and a grade II/VI pansystolic murmur heard at the left sternal edge and apex with radiation to the axilla. There was no fever or stigmata of peripheral embolic phenomena, and the remainder of the examination was normal.

Laboratory workup revealed a CD4 count of $9 \times 10^6/L$ and a viral load measured at 43,000 copies/dL. Two blood cultures from the referring hospital were positive for methicillin-sensitive Staphylococcus aureus. Numerous subsequent cultures remained negative.

Repeat echocardiogram (see Fig. 1) confirmed a large left atrial mass attached by a stalk to the interatrial septum impinging on mitral valve closure with associated mitral regurgitation. Additionally, there was functional mitral stenosis resulting from prolapse of the mass across the mitral valve during ventricular diastole, with a mean mitral inflow gradient of 5 mm Hg.

FEATURED ECG

A Narrow Complex Tachycardia in a Man With Palpitations for Many Years

Julia H. Indik, MD, PhD

A 44-year-old man was referred for evaluation of palpitations. He described these as a sensation of regular fast beats, abrupt in onset. These palpitations had been occurring for at least 20 years. However, in the last year his symptoms had worsened despite medical therapy with verapamil. He had no structural heart disease, and his baseline electrocar-

tachycardia, wherein the P wave is generally closer to the previous QRS than the following QRS. Atrial tachycardia usually presents as a "long R-P" tachycardia wherein the P wave is closer to the following QRS rather than the preceding one. In typical ANVRT, the P wave is generated by fast

Early Gastric Cancer

Early gastric cancer refers to tumor confined to the mucosa or submucosa, regardless of the presence or absence of metastasis. This disease entity carries an extremely good prognosis and is particularly prevalent in Japan, where mass screening of gastric cancer is performed. This entity is estimated to represent up to 65% of gastric cancers diagnosed in Japan. A 5-year survival rate of more than 90% was reported in Japan after gastrectomy and removal of primary and secondary lymph nodes. [106](#)

The JRS GC classified early gastric cancer into three types based on macroscopic appearances [107](#) (Fig. 69-9). JRS GC type I is an exophytic lesion, type II is flat (or superficial), and type III is an ulcerated or depressed lesion. Type II is further divided into three subtypes, depending on whether it is elevated (IIa), flat (IIb), or depressed (IIc). In addition, combined types have been defined to include complex configurations. The protruded-type (type I and type IIa) with a diameter of less than 25 mm, and the excavated type (type IIc), with a diameter of less than 20 mm, seldom produce lymph node metastasis. Moreover, the depth of tumor invasion also bears important prognostic significance. The incidence of nodal metastasis of intramucosal and submucosal cancer is reported to be 3% and 20%, respectively. [108](#) Other parameters that may determine the rate of lymph node metastases are the size of the tumors and the presence of

P. 1424

ulcerations. Distant metastasis is uncommon in early gastric cancer.

FIGURE 69-9. Classification of early gastric cancer by the Japanese Gastroenterological Endoscopy Society. (From Japanese Research Society for

Abstract

BACKGROUND & AIMS: Helicobacter pylori-infected gastric mucosa evolves through stages of chronic gastritis, intestinal metaplasia (IM), glandular atrophy (GA), and dysplasia before carcinoma develops. We studied if H. pylori eradication would alter the course of premalignant histologic changes in the stomach. **METHODS:** Volunteers from the Yantai County in China underwent upper endoscopy with biopsy specimens obtained from the antrum and corpus. H. pylori-infected subjects were randomized to receive either a 1-week course of omeprazole, amoxicillin, and clarithromycin (OAC) or placebo. At 1 year, endoscopies with biopsies were repeated. **RESULTS:** A total of 587 H. pylori-infected subjects were randomized to OAC (n = 295) and placebo (n = 292). At 1 year, H. pylori was eradicated in 226 subjects assigned to OAC. In the placebo group, 245 patients remained H. pylori infected. Analysis of paired samples obtained from the same patients showed that acute and chronic gastritis decreased in both the antrum and corpus after H. pylori eradication (P < 0.001) and activity of IM decreased in antrum (P = 0.014). In the H. pylori-infected group, antral biopsy specimens had more pronounced acute gastritis (P = 0.01), whereas corpus specimens showed increased acute and chronic gastritis (P < 0.001) and a marginal increase in GA (P = 0.052). When histologic changes were compared between the 2 groups, decrease in acute and chronic gastritis was more frequent after H. pylori eradication (P < 0.001) but changes in IM were similar. In the H. pylori-infected group, increase in GA was seen in the corpus (P = 0.01). **CONCLUSIONS:** At 1 year, H. pylori eradication is beneficial in preventing progression of pathologic changes of the gastric mucosa.

PATHOLOGICAL FEATURES

Part of "[CHAPTER 69 - TUMORS OF THE STOMACH](#)"

Adenocarcinoma accounts for 95% of the stomach cancers, whereas squamous cell carcinoma, carcinoid tumors, leiomyosarcoma, and lymphoma constitute the rest of the gastric tumors. Macroscopically, gastric cancers can be broadly categorized by their location and appearances. Categorization of tumors into proximal (cardia) versus distal (including body and antrum) cancers bears major etiologic significance. Distal cancers are more common in areas with a high gastric cancer

P. 1421

incidence, whereas cardia cancers are more prevalent in whites from populations with a low background incidence of gastric cancer. The former may be closely related to chronic *H pylori* infection, whereas the latter is often the consequence of chronic gastroesophageal reflux disease and Barrett esophagus. Of interest, the fall in incidence of gastric cancer is more of the result of the decline in distal gastric cancer. By contrast, the incidence of gastroesophageal junction carcinomas is actually increasing in the United States⁴ and in many other developed countries.

PATHOLOGICAL FEATURESPart of "CHAPTER 69 - TUMORS OF THE STOMACH"

Adenocarcinoma accounts for 95% of the stomach cancers, whereas squamous cell carcinoma, carcinoid tumors, leiomyosarcoma, and lymphoma constitute the rest of the gastric tumors. Macroscopically, gastric cancers can be broadly categorized by their location and appearance. Categorization of tumors into proximal (cardia) versus distal (including body and antrum) cancers bears major etiologic significance. Distal cancers are more common in areas with a high gastric cancer incidence, whereas cardia cancers are more prevalent in whites from populations with a low background incidence of gastric cancer. The former may be closely related to chronic H pylori infection, whereas the latter is often the consequence of chronic gastroesophageal reflux disease and Barrett esophagus. Of interest, the fall in incidence of gastric cancer is more of the result of the decline in distal gastric cancer. By contrast, the incidence of gastroesophageal junction carcinomas is actually increasing in the United States⁴ and in many other developed countries.

Gastric tumors can also be classified by their gross appearances. The macroscopic appearance has been classified by Borrmann into four types (Fig. 69-5). Type I represents polypoid lesions without necrosis or ulceration, type II encompasses fungating cancers that may contain superficial ulceration, type III represents ulcerated lesions infiltrating the gastric wall, and type IV tumors are diffusely infiltrating tumors or linitis plastica lesions. There is considerable overlap among the different subtypes, and this typing system does not appear to correlate with histological typing. Approximately 40% to 50% of tumors are fungating or polypoid in appearance, and similar numbers of tumors are ulcerative. Linitis plastica is an aggressive infiltrating tumor consisting of high-grade tumor cells accompanied by a marked desmoplastic reaction that results in a rigid stomach resembling a leather bottle. This form of tumor spreads through the submucosa and is associated with worse prognosis.

FIGURE 69-5. Macroscopic appearance of tumor as classified by Borrmann. (A) Polypoid. (B) Fungating with surface ulceration and hemorrhage. (C) Ulcerated without major lumen component. (D) Infiltrative. (From Borrmann R. Geschwulste des Magen und Duodenums. In: Henke F, Lunbarsch O, eds. Handbuch der speziellen pathologischen Anatomie und Histologie, vol 4. Berlin: Julius Springer, 1926:812.)

Microscopically, several histological classifications of gastric cancer are used. The most widely used classification, proposed by Lauren,⁸⁷ broadly divides gastric cancer into diffuse and intestinal types (Fig. 69-6, see also Color Fig.

69-6). Despite its simplicity, this classification categorizes tumors into two distinct types with contrasting epidemiology, etiology, and prognosis. The intestinal type is named by its histological morphology, and the diffuse type is characterized by its biologic behavior. Intestinal-type cancer is characterized by cohesive neoplastic cells forming glandular tubular structures, whereas diffuse-type cancer shows sheets of epithelial cells or cells scattered in a stromal matrix without evidence of gland formation. Diffuse cancers may contain signet-ring cells. Intestinal-type cancer is more common in the distal stomach and is often preceded by preneoplastic stages such as intestinal metaplasia. It is more prevalent in regions with a high background incidence of gastric cancer and is generally associated with a better surgical outcome than the diffuse type. Nonetheless, approximately 5% to 10% of tumors remain unclassified, and they are called mixed-type tumors. These unclassified tumors are usually regarded as diffuse-type tumors during clinicopathological evaluations.

series; response to neoadjuvant chemotherapy was found to be the single most important predictor of overall survival. [181](#)

In addition to the administration of chemotherapeutic agents by the systemic route, antitumor drugs can be delivered intraperitoneally. The potential benefit of intraperitoneal chemotherapy is based on the ability to control locoregional tumor recurrence after curative resection. Hagiwara and colleagues [182](#) evaluated the use of intraperitoneal mitomycin C adsorbed to activated charcoal in high-risk patients after curative resection. There was a highly significant difference in 2-year survival (68.6% versus 26.9%) favoring the use of this regimen. A prospective randomized [183](#) of early postoperative intraperitoneal chemotherapy as adjuvant therapy in resectable gastric cancer also showed significant improvement in 5-year survival rate in a subset of patients with stage III disease. [183](#) The effects of intraperitoneal chemotherapy remain to be substantiated by further studies.

Radiotherapy

Gastric carcinoma is relatively resistant to radiotherapy. Radiotherapy includes both external beam and intraoperative radiotherapy. The British Stomach Cancer Group [184](#) found that postoperative radiotherapy in addition to surgery did not confer any benefit in survival. The 5-year survival in patients receiving surgery plus radiotherapy and surgery alone was 12% and 20%, respectively. Conversely, intraoperative radiotherapy is frequently given in Japan. [185](#) Although it appeared to prolong survival for patients with stage II and III disease, this therapy needs further evaluation.

Ovid Web Gateway will soon have a new look!

We're updating our interface to reflect a more contemporary, cleaner presentation with easier, more intuitive navigation for both experienced and novice users.

To help you prepare for these exciting changes to Ovid Web Gateway, we've created this Resource Center as your main source for all related communication and announcements, training materials, screen shots, and much more. As we update our training materials, you'll be the first to access the new online tutorial and quick reference cards.

Be sure to bookmark this site and visit it often to get the latest news and status of our progress. If you have any immediate questions, contact us at support@ovid.com.

We rely on ideas and feedback from our customers when we make decisions to improve our products and services. We're confident that you'll find the new interface clean and easy to navigate.
